Introduction

Why did the chicken cross the road? To get to the other side. So then why did the frog cross the road? Because he knew he was much braver than some chicken and if the chicken could do it, so could he. Frog Jump is just that, reaching the other side of the road amongst a busy highway and avoiding getting killed by these fast paced cars! Work hard and get as many wins as you can. Try to get the fastest time as well! If you think the game is too easy, then feel free to step up the difficulty and make it harder than ever! With all that you can do in this game, it will be hard to put it down!

Purpose of the Game

The purpose of this game is to be able to reach the finish position while jumping through an obstacle of cars. When you turn on the game, you will be taken to a menu screen. You are able to see the wins/losses as well as the high score. You can change the color of the frog in the menu screen as well. When ready, press up or down to get you to the gameplay screen. You must wait for the screen to setup and for the cars to get going. After waiting a few seconds you can go. You can then jump around and make your way through a never ending maze of cars. Time your moves right and navigate your frog to the finish position at the end. Upon completion you will add to your wins and if your current time is faster than the older time then you obtain the new high score. If your frog gets hit by a car then you lose and will be taken back to the menu screen.

Design Overview

Requirements:

1. Display the menu screen.
2. Be able to see the high score and the wins/losses.
3. Change the color of the frog in the menu screen
4. Enter game play mode.
5. By pushing the buttons, have the frog jump to the desired square.
6. Have cars travel in patterns automatically.
7. When the frog gets hit by the car, the player loses.
8. When the frog gets to the finish position, the player wins.
9. Enable music for the menu and during game play.
10. Enable sounds for frog jumps, winning and losing.

Hardware:

1. Tiva C series TM4C123GH6PMI Microcontroller
2. 3.2" TFT LCD Display Module
3. 3.2" LCD adapter, 16-bit to 8-bit

4. Analog test board
5. 5 volt power supply
6. 4 push buttons

Software:

Things that need to get programmed:

1. Menu screen
 - a. Display the Title
 - b. Display the High Score
 - c. Display the Wins/Loses
 - d. Display instructions for buttons for screen
 - e. Display the frog
 - f. Display two cars, one moving and one staying still.
 - g. Play music
 - h. Enable button pushes to trigger events
 - i. Up and down start game
 - ii. Left and right change the frog's color
2. Gameplay Screen
 - a. Display background
 - b. Display boundaries
 - c. Display Start and finish position
 - d. Play music
3. The Frog
 - a. Update position of the frog
 - i. Up button jumps frog up
 - ii. Down button jumps frog down
 - iii. Right button jumps frog right
 - iv. Left button jumps frog left
 - b. Create frog image
 - c. Create position for frog
4. The Cars
 - a. Enable automatic updates of car paths
 - b. Create car image
 - c. Create positions for each car
 - d. Create patterns for cars
5. Winning State
 - a. Display Win
 - b. Return to menu
6. Losing State
 - a. Display Lose
 - b. Return to menu

Design Details

Hardware:

Port Configuration:

PA2 – SCLK on DAC

PA3 – CS on DAC

PA4 – DEN on LCD module

PA5 -- DDIR on LCD module

PA6 – DLE on LCD module

PB0 – Data0 on LCD module

PB1 – Data1 on LCD module

PB2 – Data2 on LCD module

PB3 – Data3 on LCD module

PB4 – Data4 on LCD module

PB5 – Data5 on LCD module

PB6 – Data6 on LCD module

PB7 – Data7 on LCD module

PC4 – CS on LCD module

PC5 – WR on LCD module

PC6 -- RD on LCD module

PC7—RS on LCD module

PE0 – Push button (up)

PE1 – Push button (down)

PE2 – Push button (left)

PE4 – Push button (right)

PE3 – ACD2 on Analog board

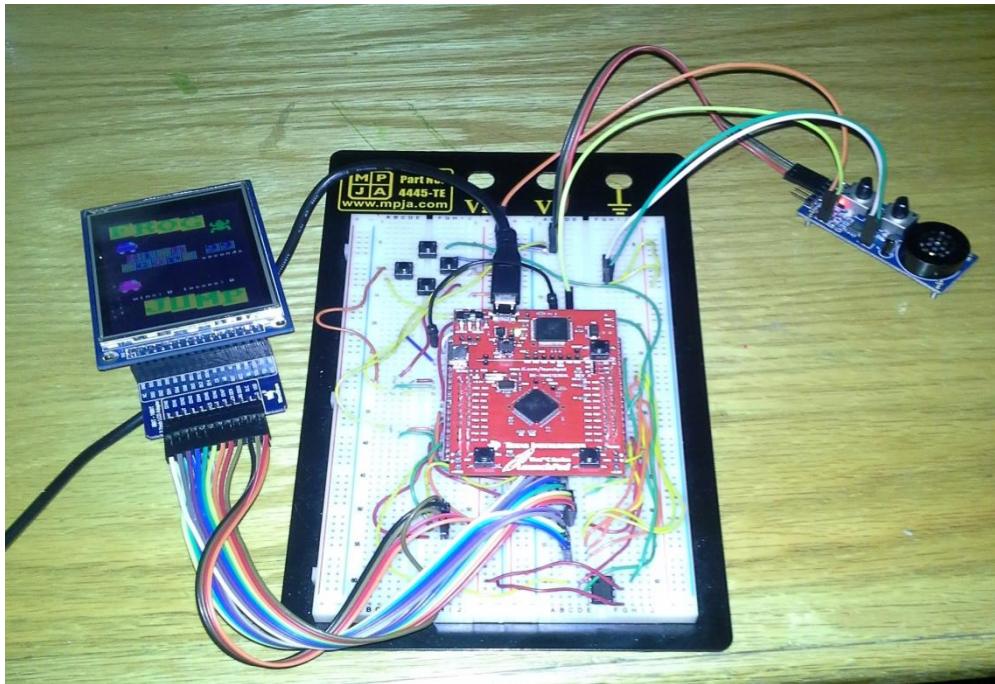

PF4 – RST on LCD module

UBUS – VDD on DAC

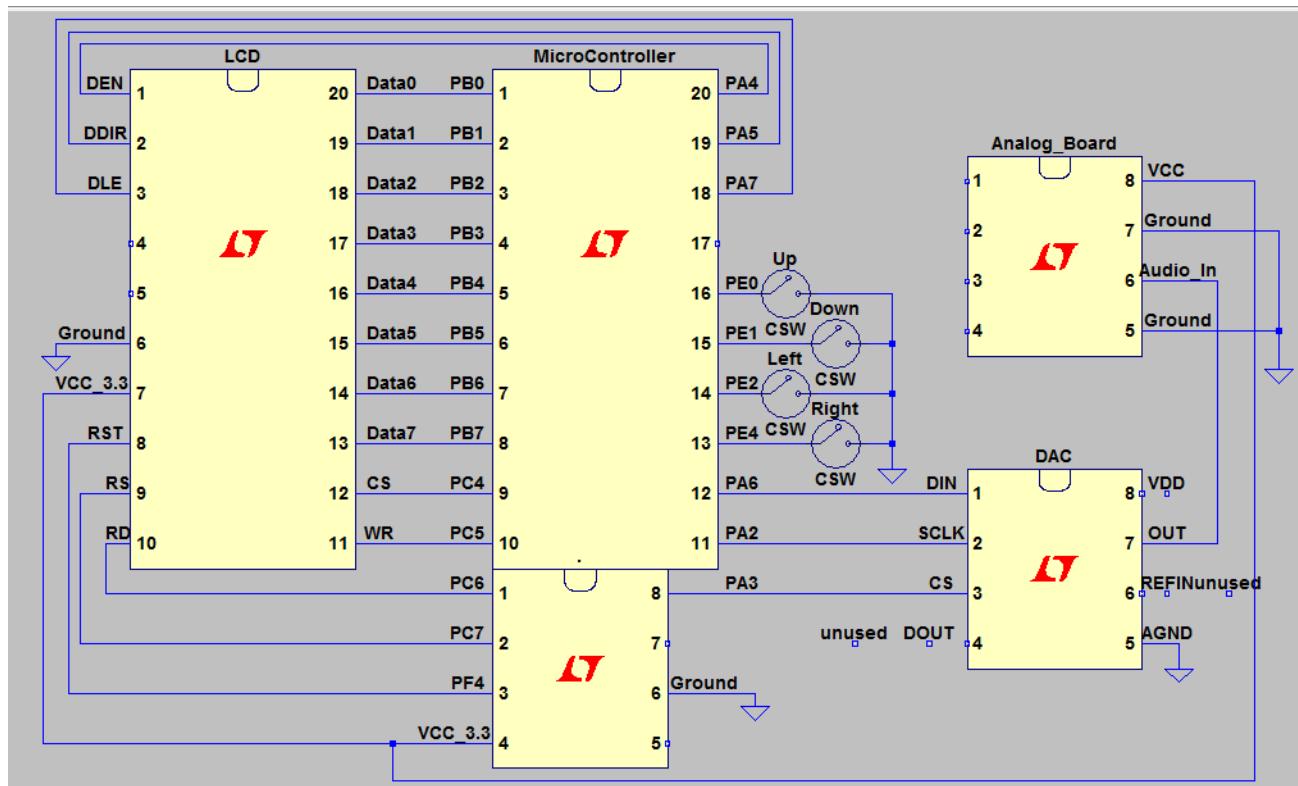

VCC (3.3V) – VCC on LCD module, VCC on analog board, VCC for speaker

Hardware Setup:

Actual Setup:

Hardware Schematic:

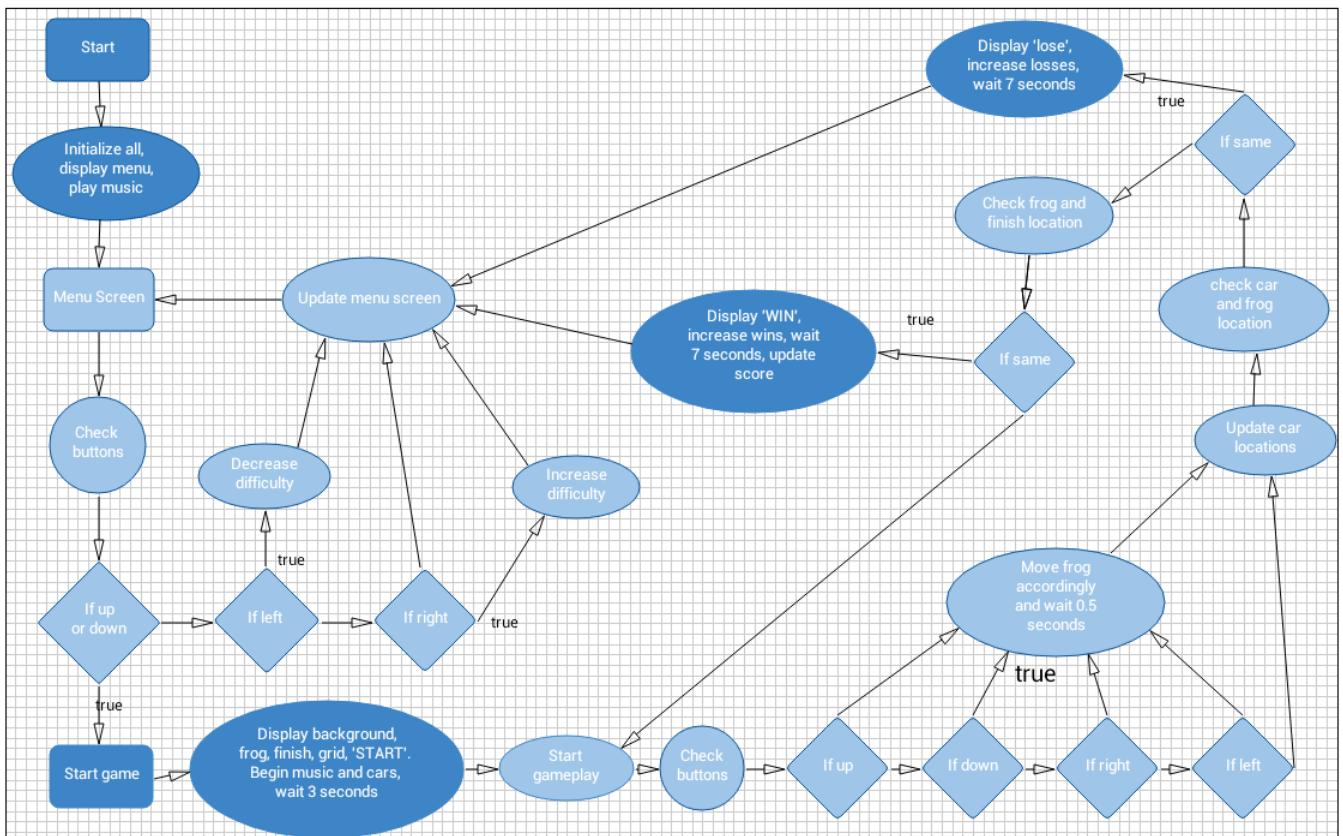

Explanation of the Setup:

I decided to try to follow what we did in the labs. From our final lab we were able to use the LCD screen with the DAC and analog board. I tried to keep these settings the same. On top of that I needed to add 4 buttons. I struggled getting the buttons to work so I had to change some things from the last lab's setup. I kept all of port B to be the data pins for the LCD screen as well as all of port C4-C7 for the CS, RS, RD, and WR, with port PF4 as the RST. From the last lab we used ports E0-E2 for the DDIR, DEN, DLE but I had to switch them to PA4, PA5, and PA7. I then kept the DAC ports the same, being PA2 for SCLK, PA3 for CS for the DAC, and PA6 for DIN. I kept PE3 being used for the Analog board and used the pins around it for the buttons, those pins being PE0, PE1, PE2, PE4. I then tied the VCC and GND as needed from each piece of equipment to the micro controller. I also needed to use a power supply to power the analog board.

Software:

The Flow Chart:

Explanation of the Flow Chart:

Upon turning on the game or reset, we must initialize everything that we are using. We first initialize the Tiva C Series Microcontroller with its various timers, GPIO ports, interrupts, and the DAC. For more information regarding the setup see the Hardware section under Design Details. After that we initialize the LCD module for displaying data only. We do not make use of the touchscreen. Once we have everything initialized, we display the menu on the LCD screen and play some background music. We wait in this state until one of the buttons is pushed. When the left or right button is pushed, we change the color of the frog. When either the up or down button is pushed, we continue with the game.

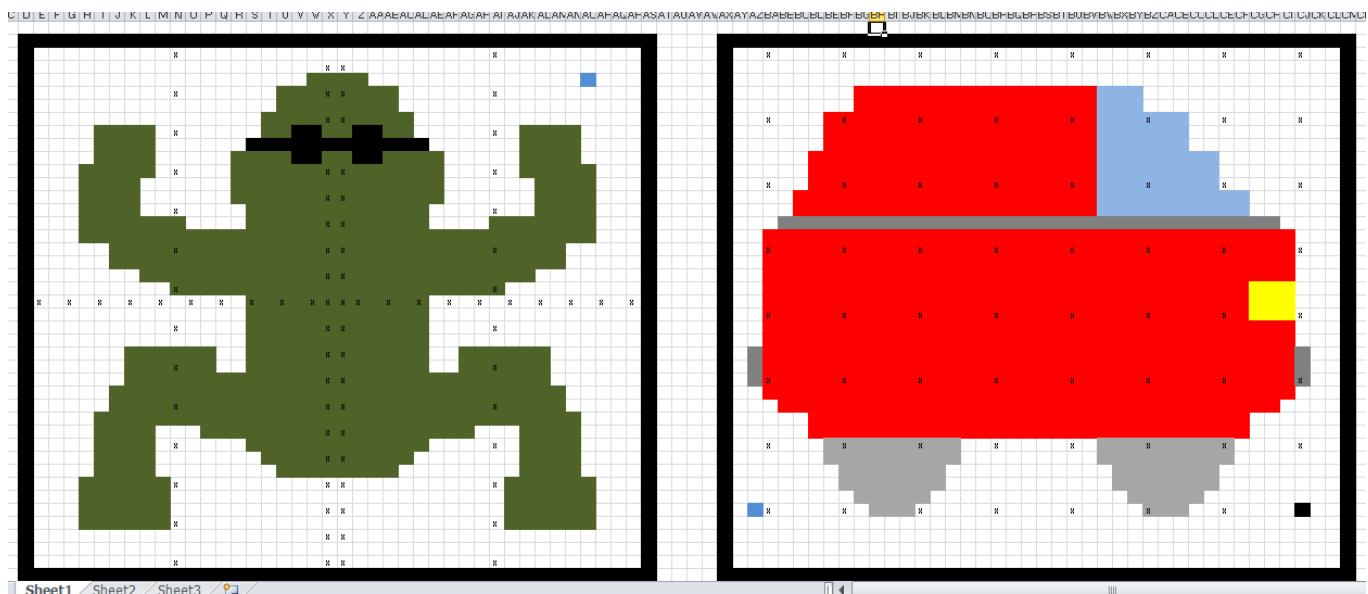

Before we start the gameplay, we must setup how everything is displayed. We display the background, followed by the finish position, the start position, the frog, and the boundaries. We enable the cars to start their patterns. We also display ‘START’ for 3 seconds and we do not allow the player to start playing until the ‘START’ is gone. Once the “START” is gone, we display a “GO” around the frog and set a flag that will enable the buttons to work.

After the ‘START’ is gone, the player is then free to jump around and avoid the cars. To do this we must check to see which buttons are being pushed. If the up button is pushed then we have the frog jump up and face up. We mimic this with the down jumping the frog down and facing down, with the right, and with the left. The frog limited to jump within the boundaries set, which are the top and bottom of the screen, as well as the middle portion of the screen. After the frog either jumps in any direction or sits there, the cars get updated. Each track gets updated and the car moves to its new location. After the frog and the cars are updated, we must check to see if the car has run over the frog. If this has happened we immediately display ‘LOSE’ and wait a little bit before we move back to the menu screen. We then must update the screen and increase the number of losses. If the frog doesn’t get hit and makes his way to the finish position, then we immediately display ‘WIN’ and wait a little bit before we go back to the menu screen. We update the menu screen to include the new amount of wins as well as the high score. We then repeat the menu screen state.

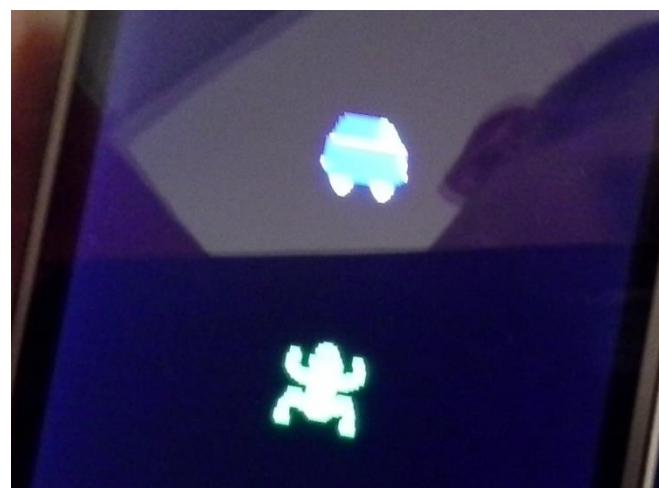

Testing

Creating images:

When I thought about making the images, I started out using Excel. I created a 40X40 area that would be designated for the frog and another for the car. I made each square about the same size. I then started filling in areas to design the frog. I made it symmetric. I did something similar with the car. I designed it as I wanted. Here is the excel picture of it:

From this I was able to create code that would create a lot of boxes for each part of the frog or car. I would feed the function the coordinate where I wanted the box, and then I would pass in how long in the x-direction as well as how long in the y-direction. We would also throw in the color that we wanted for most of the frog or car. After doing so this is how I got the car and frog to appear on the screen:

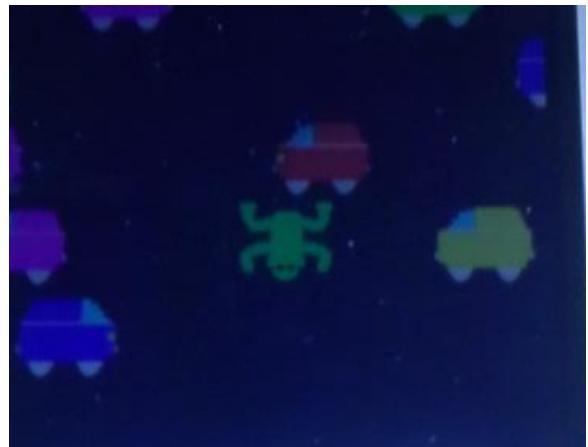

Moving the Frog:

Once I got the buttons working, I started working on the frog's movement. I created 4 different directions for the frog so I could keep the position of the frog relative for each movement. For each button I either added or subtracted from either the X coordinate or Y coordinate and saved this value as the new X and Y coordinate. After we push a direction, we clear the frog completely at its current position, we increment or decrement the X or Y depending on which button is pressed. We then draw the specific direction of the frog. Here are a pictures of each direction:

Frog facing up:

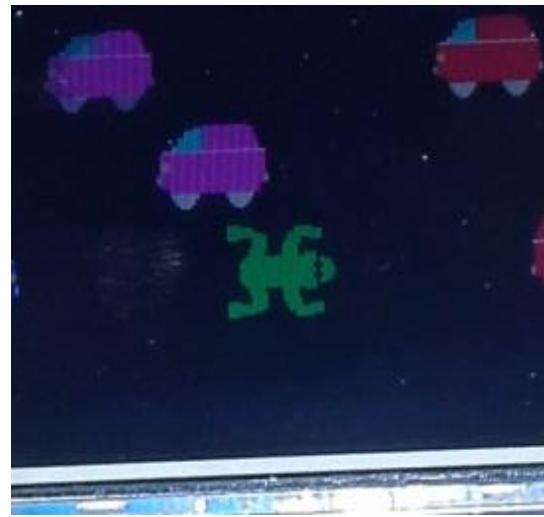

Frog facing down:

Frog facing left:

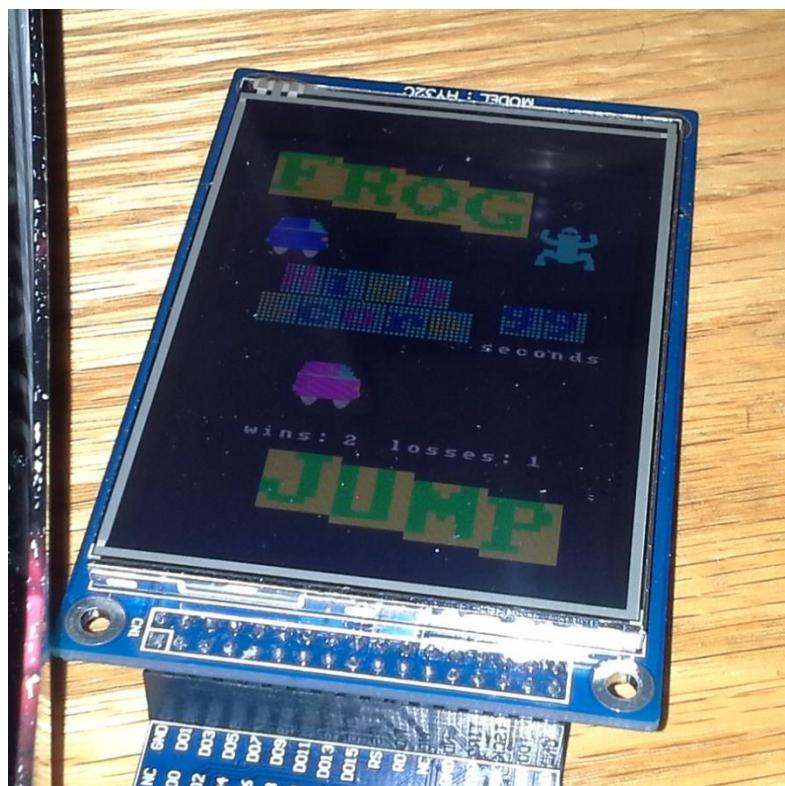

Frog facing right:

Creating the Menu Screen:

There were a handful of things I wanted in the screen. I needed to put the title. I needed to display the “High Score” followed by the actual high score. For design I put a picture of a car. I also decided it would be fun to have a car drive around, so I was able to get that working. I decided to put a frog on the screen. I made the frog be able to change color and that the color that the frog is when starting the game is the color of the frog during the game play. I also decided it would be fun to denote how many wins and losses the player has and I would display “wins” followed by how many and also “losses” followed by how many. Here is how it looks:

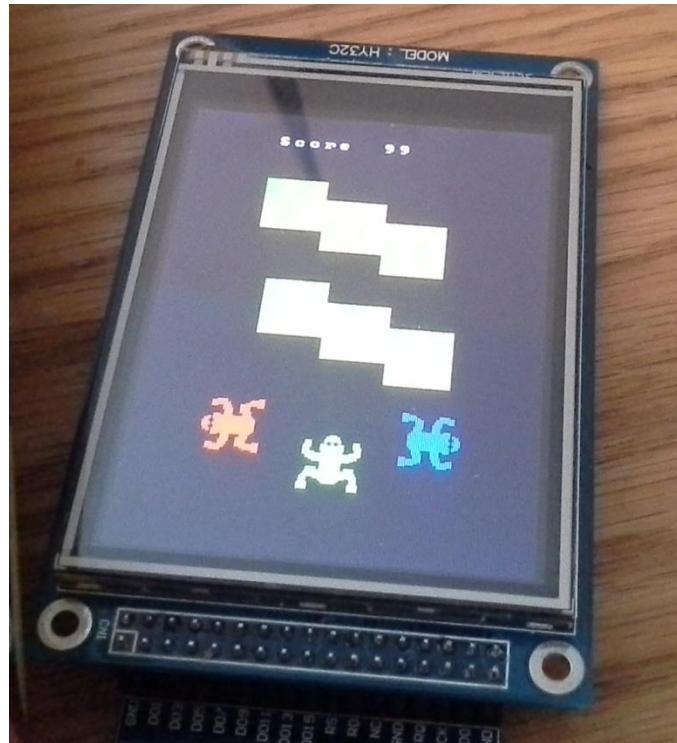

Creating the Car paths:

The goal of this was to try and get different patterns and different speeds of the cars going in different directions. I was able to get half of the cars going one way and the other half going the other direction. I also was able to get the cars in different colors. I had trouble with the speed so I wasn't able to get the cars moving at different speeds. But I was able to get the patterns of the cars to be different. I had the cars regenerate at different rates which makes the game change as time goes by. These are a few pictures of the screen:

Win and Lose State:

Win State: For the design I decided to do a couple of things. Once the frog's coordinates are the same as the finish position, we enter this state. We display a "You Win" signifying that the player won. We also must display the time it took the player to win. So we display "Score" followed by the time it took. I decided to add a couple of frogs in the screen because the frog successfully crossed the road. We also wait a couple of seconds before we go back to the menu screen. I organized them as shown:

Lose State: We enter this state when the frog's coordinates match up with any of the car's coordinates. When this happens we display a "Game Over", signifying that the player has lost. We also display a bunch of cars because the cars ran the frog over. We wait a few seconds before we go back to the menu screen. I organized it as follows:

Conclusion

Some of the problems I faced:

- 1) I had a problem with the speed of the cars. Because of all of the code that I was running, I couldn't update the cars as fast as I wanted to. I tried to make it faster but it wasn't going as fast as I hoped. So I tried to update the cars faster by reducing the amount of cars to update. When I did this the cars moved twice as fast, but that was still slower than I wanted. I then tried to change the way I update the cars. I drew the first eight pixels of the car and let them drag so I was only really updating an 8 x 40 pixel area instead of a 40 x 40 pixel area. Sadly this didn't increase the speed by that much, but it made them slightly faster.
- 2) I struggled with getting the ports set up correctly for the push buttons. I initially tried to set up port D. After I tried this and tried to get them working, I realized this port doesn't work as I had hoped. I later found out that port D0 and port D1 are linked with some of the port B pins. I then tried to switch to port A but I wasn't having luck with that. I then switched to port E and tried to get it working. It was working but I struggled to get the right pins. The simulator didn't help and threw me off a lot because it wouldn't show the data on port E correctly and it changed almost every time I reran the debugger. After a lot of changing I found out that the simulator doesn't show the button pushes but that they work regardless of what the simulator shows. I ended up putting the buttons on port E0, E1, E2, and E4, reserving E3 for the Analog board. Once I realized this fact, then things worked out really well and I implemented functions accordingly for the menu screen and the game screen.

Besides these problems, most of the other stuff went normal and just took time to get things rolling. I enjoyed working on the game and working on some of the bugs that came up and getting everything in a working order. I enjoyed this project and look forward to creating more and more projects like this.

Code

My Main.c

```
#include "LCDfinal.H"

int main(void)
{
    unsigned short bg = black;
    lcdPortConfig();
    lcdInit();
    clearLCD(bg);
    //SSIOInit();
    //initial values
    while(1)
    {
        menuScreen();
    }
}
```

My FrogGame.h

```
/* function prototypes for SSD1289 LCD on Tiva C Launchpad */

// 16-bit RGB values for some common colors
#define white      0xFFFF
#define black      0x0001
#define gray       0xF7DE
#define blue       0x001F
